

#### SNS COLLEGE OF TECHNOLOGY

# Coimbatore-35. An Autonomous Institution

Accredited by NBA – AICTE and Accredited by NAAC – UGC with 'A++' Grade Approved by AICTE, New Delhi & Affiliated to Anna University, Chennai

**COURSE NAME : OPERATING SYSTEMS** 

II YEAR/ IV SEMESTER

#### UNIT – II PROCESS SCHEDULING AND SYNCHRONIZATION

**Topic: Dead Lock** 

Dr.B. Vinodhini

Associate Professor

Department of Computer Science and Engineering

#### **Deadlock Detection**

- Allow system to enter deadlock state
- Detection algorithm
- Recovery scheme

#### **Single Instance of Each Resource Type**

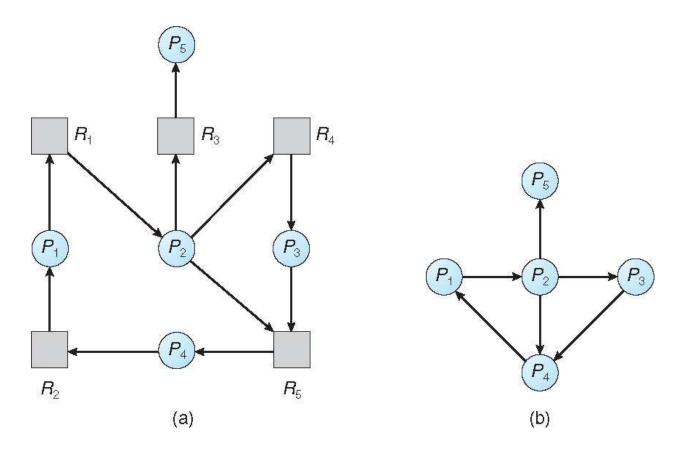

- Maintain wait-for graph
  - Nodes are processes
  - $P_i \rightarrow P_j$  if  $P_i$  is waiting for  $P_j$
- Periodically invoke an algorithm that searches for a cycle in the graph. If there is a cycle, there exists a deadlock
- An algorithm to detect a cycle in a graph requires an order of  $n^2$  operations, where n is the number of vertices in the graph

#### **Resource-Allocation Graph and Wait-for Graph**

Resource Allocation Graph Corresponding wait-for graph
B. Vinodhini

## **Several Instances of a Resource Type**

- $\blacksquare$  Available: A vector of length m indicates the number of available resources of each type
- Allocation: An  $n \times m$  matrix defines the number of resources of each type currently allocated to each process
- Request: An  $n \times m$  matrix indicates the current request of each process. If Request[i][j] = k, then process  $P_i$  is requesting k more instances of resource type  $R_i$ .

### **Detection Algorithm**

- 1. Let *Work* and *Finish* be vectors of length *m* and *n*, respectively Initialize:
  - (a) Work = Available
  - (b) For i = 1,2, ..., n, if Allocation<sub>i</sub> ≠ 0, then
     Finish[i] = false; otherwise, Finish[i] = true
- 2. Find an index *i* such that both:
  - (a) Finish[i] == false
  - (b) **Request**<sub>i</sub>≤ **Work**

If no such *i* exists, go to step 4

## **Detection Algorithm (Cont.)**

- 3. Work = Work + Allocation; Finish[i] = true go to step 2
- 4. If Finish[i] == false, for some i,  $1 \le i \le n$ , then the system is in deadlock state. Moreover, if Finish[i] == false, then  $P_i$  is deadlocked

Algorithm requires an order of  $O(m \times n^2)$  operations to detect whether the system is in deadlocked state

### **Example of Detection Algorithm**

- Five processes  $P_0$  through  $P_4$ ; three resource types A (7 instances), B (2 instances), and C (6 instances)
- Snapshot at time T<sub>0</sub>:

	<u>Allocation</u>	<u>Request</u>	<u>Available</u>
	ABC	ABC	ABC
$P_0$	010	000	000
$P_1$	200	202	
$P_2$	303	000	
$P_3$	211	100	
$P_4$	002	002	

Sequence  $P_0$ ,  $P_2$ ,  $P_3$ ,  $P_4$ ,  $P_4$  P with the sum of  $P_4$   $P_4$  P

### **Example (Cont.)**

P<sub>2</sub> requests an additional instance of type C

	<u>Request</u>		
	ABC		
$P_0$	000		
$P_1$	202		
$P_2$	0 0 1		
$P_3$	100		
$P_4$	002		

- State of system?
  - Can reclaim resources held by process  $P_0$ , but insufficient resources to fulfill other processes; requests
  - Deadlock exists 12000 sisting by seass 181, 182, 183, and 184 B. Vinodhini

### **Detection-Algorithm Usage**

- When, and how often, to invoke depends on:
  - How often a deadlock is likely to occur?
  - How many processes will need to be rolled back?
    - one for each disjoint cycle
- If detection algorithm is invoked arbitrarily, there may be many cycles in the resource graph and so we would not be able to tell which of the many deadlocked processes "caused" the deadlock.

#### **Recovery from Deadlock: Process Termination**

- Abort all deadlocked processes
- Abort one process at a time until the deadlock cycle is eliminated
- In which order should we choose to abort?
  - 1. Priority of the process
  - 2. How long process has computed, and how much longer to completion
  - 3. Resources the process has used
  - 4. Resources process needs to complete
  - 5. How many processes will need to be terminated
  - 6. Is process interactive or batch?

#### **Recovery from Deadlock: Resource Preemption**

- **Selecting a victim** minimize cost
- Rollback return to some safe state, restart process for that state
- **Starvation** same process may always be picked as victim, include number of rollback in cost factor
