(An Autonomous Institution)

Approved by AICTE, New Delhi, Affiliated to Anna University, Chennai

Accredited by NAAC-UGC with 'A++' Grade (Cycle III) &

Accredited by NBA (B.E - CSE, EEE, ECE, Mech & B.Tech.IT)

COIMBATORE-641 035, TAMIL NADU

## DEPARTMENT OF FOOD TECHNOLOGY

### 23FTT204- BIOCHEMISTRY & NUTRITION

#### UNIT 2 -TOPIC 4

Shortening power :

Fats perform a shortening function in the dough to deliver desirable textural properties in a food product. Shortening acquires its name from the truth that fat by its extremely nature coats the protein molecules in flour, making it hard for them to join and make a stretchy material called gluten. Gluten strands that do develop are “shortened”. Otherwise, more gluten could be developed and successively, lead to undesirable hard or chewy cookie texture. Subsequently, for various texture prerequisites, diverse shortenings will be chosen.

The level of shortening developed by a fat or oil in a given product relies on the surface area of the flour particles covered with the aid of the fat. It is usually considered that unsaturated fatty acids have more prominent covering power compared to saturated fatty acids. Thereby, variations in the shortening power of different fats probably clarified by their level of unsaturation.

Smoke Point:

The smoke point, also referred to as the burning point, is the temperature at which an oil or fat begins to produce a continuous bluish smoke that becomes clearly visible, dependent upon specific and defined conditions. Smoke point values can vary greatly, depending on factors such as the volume of oil utilized, the size of the container, the presence of air currents, the type and source of light as well as the quality of the oil and its acidity content, otherwise known as free fatty acid (FFA) content. The more FFA an oil contains, the quicker it will break down and start smoking. The lower the value of FFA, the higher the smoke point. However, the FFA content typically represents less than 1% of the total oil and consequently renders smoke point a poor indicator of the capacity of a fat or oil to withstand heat.

Temperature

The smoke point of an oil correlates with its level of refinement. Many cooking oils have smoke points above standard home cooking temperatures:

- Pan frying (sauté) on stove top heat: 120 °C (248 °F)

- Deep frying: 160–180 °C (320–356 °F)
- Oven baking: Average of 180 °C (356 °F)

Considerably above the temperature of the smoke point is the flash point, the point at which the vapours from the oil can ignite in air, given an ignition source.

The infographic features a central table titled "Smoking Points of Fats & Oils" set against a kitchen background. The table lists seven types of fats and oils, their smoke points in Fahrenheit and Celsius, and their flash points in Celsius. The background includes a tiled wall, hanging pans, a stove with a pot of boiling water, and a counter with butter and a butter tub.

Smoking Points of Fats & Oils		
Butter	200°-250°F	120°-150°C
Coconut Oil (Extra Virgin)	350°F	177°C
Sesame Oil	350°F	177°C
Lard	370°F	188°C
Olive Oil (Extra Virgin)	375°F	191°C
Canola Oil	400°F	204°C
Ghee	485°F	252°C
