#### SNS COLLEGE OF TECHNOLOGY

**Coimbatore-35 An Autonomous Institution** 

Accredited by NBA – AICTE and Accredited by NAAC – UGC with 'A++' Grade Approved by AICTE, New Delhi & Affiliated to Anna University, Chennai

# DEPARTMENT OF ARTIFICIAL INTELLIGENCE AND MACHINE LEARNING 23AMB201 - MACHINE LEARNING

II YEAR IV SEM

UNIT III – GENERATIVE MODELS AND BOOSTING

TOPIC 18, 19, 20 – Random Forest, Ensemble learning and Boosting

#### Redesigning Common Mind & Business Towards Excellence

Build an Entrepreneurial Mindset Through Our Design Thinking FrameWork

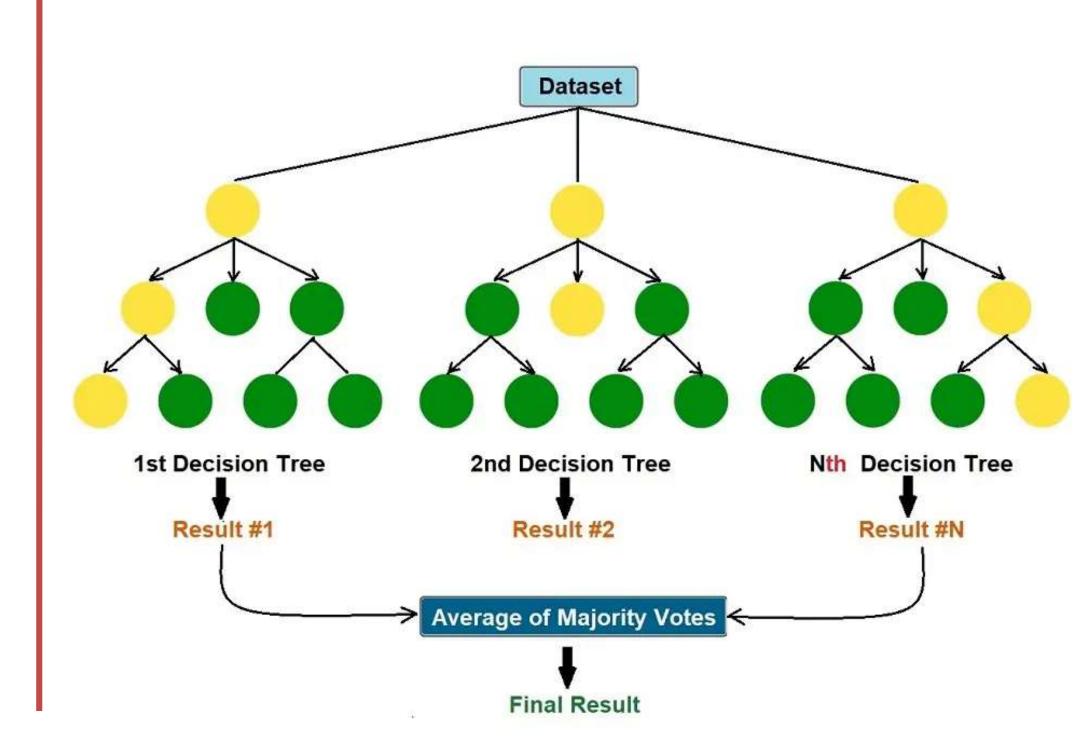

#### **Random Forest**

A Random Forest Algorithm is a supervised machine learning algorithm that is extremely popular and is used for Classification and Regression problems in Machine Learning.

Random Forest is a classifier that contains several decision trees on various subsets of the given dataset and takes the average to improve the predictive accuracy of that dataset.

### Why Random Forest?

- 1. Reduced risk of overfitting
- 2. Provides flexibility
- 3. Easy to determine feature importance

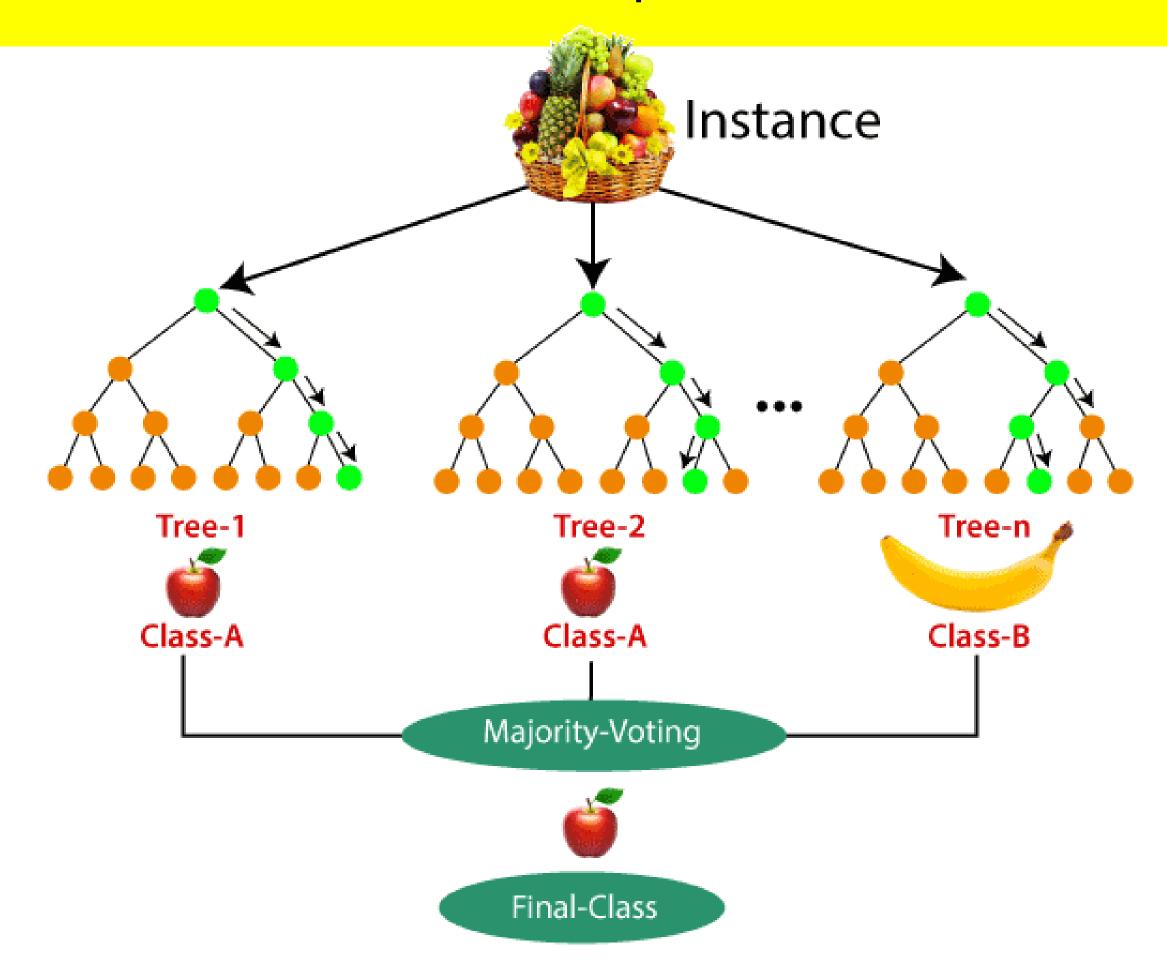

#### **How does Random Forest algorithm work?**

- 1. Step-1: Select random K data points from the training set.
- 2. Step-2: Build the decision trees associated with the selected data points (Subsets).
- 3. Step-3: Choose the number N for decision trees that you want to build.
- 4. Step-4: Repeat Step 1 & 2.
- 5. Step-5: For new data points, find the predictions of each decision tree, and assign the new data points to the category that wins the majority votes.

## Example

## Program

from sklearn.ensemble import RandomForestClassifier from sklearn.model\_selection import train\_test\_split from sklearn.metrics import accuracy\_score

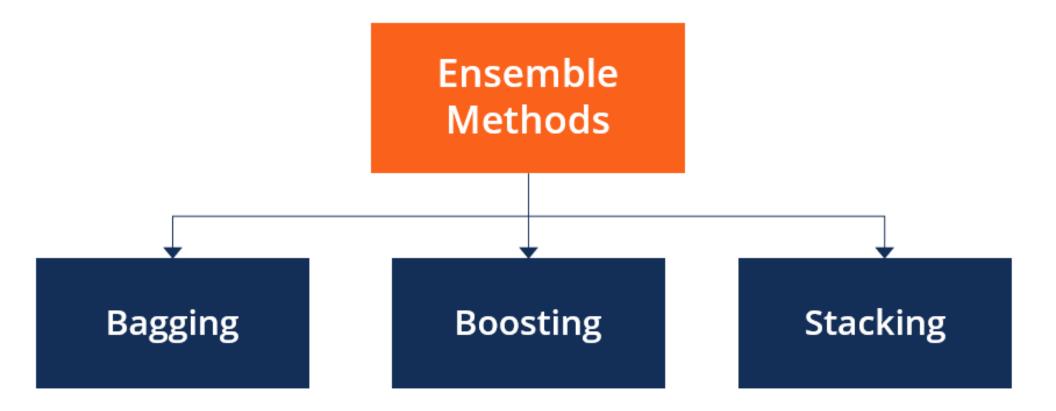

```
# Load dataset
iris = load_iris()
X_train, X_test, y_train, y_test = train_test_split(iris.data, iris.target, test_size=0.2)
# Train Random Forest
clf = RandomForestClassifier(n_estimators=100, random_state=42)
clf.fit(X_train, y_train)
# Predictions
y_pred = clf.predict(X_test)
# Accuracy
print("Accuracy:", accuracy_score(y_test, y_pred))
```

## Ensemble

**Ensemble Learning:** Combine the decisions from multiple models to improve the overall performance.

## Ensemble

- 1. An ensemble is itself a supervised learning algorithm because it can be trained and then used to make predictions.
- 2. It combine several decision trees classifiers to produce better predictive performance than a single decision tree classifier.
- 3. Main principle is to group of weak learners come together to form a strong learner
- 4. To increasing the accuracy of the model.
- 5. Ensemble helps to reduce noise, variance and bias

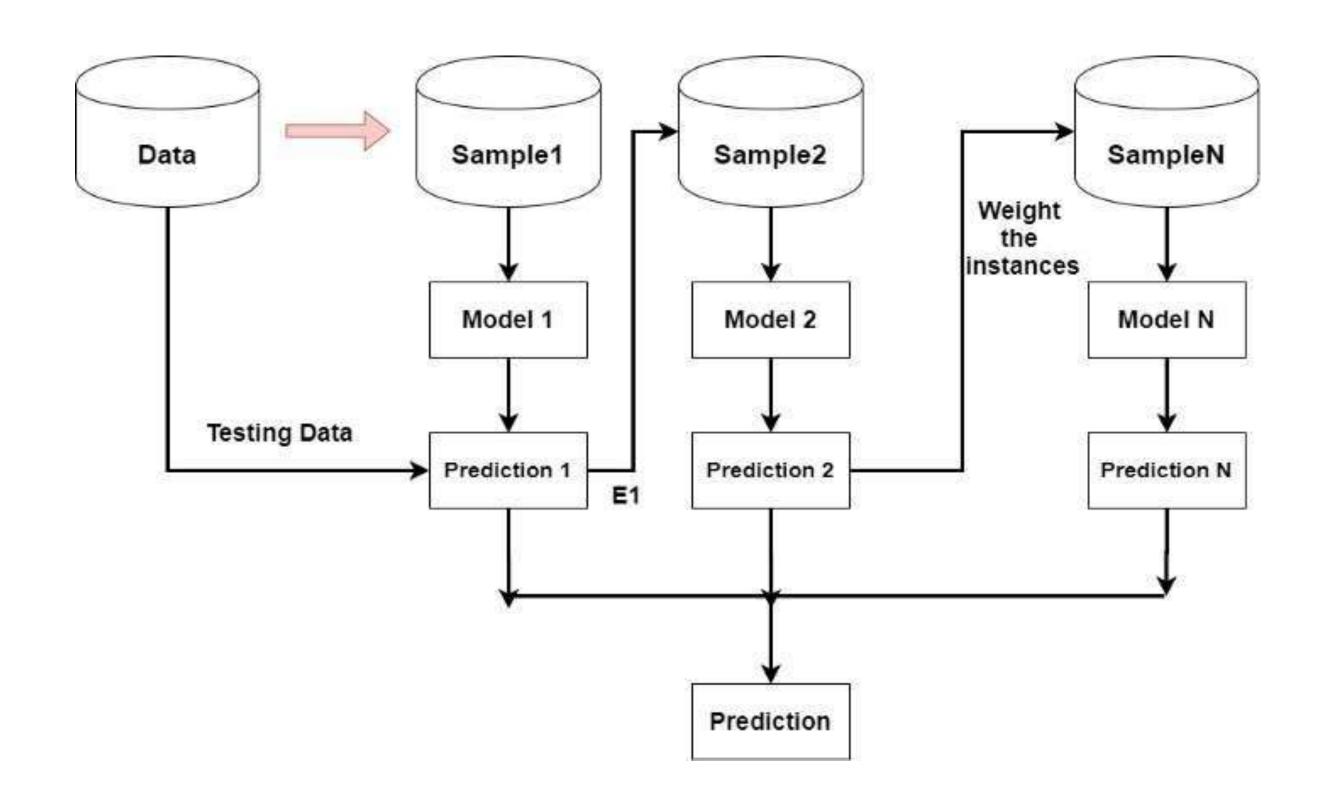

Total error can be expressed as follows:

**Total Error = Bias + Variance + Irreducible Error** 

## Ensemble

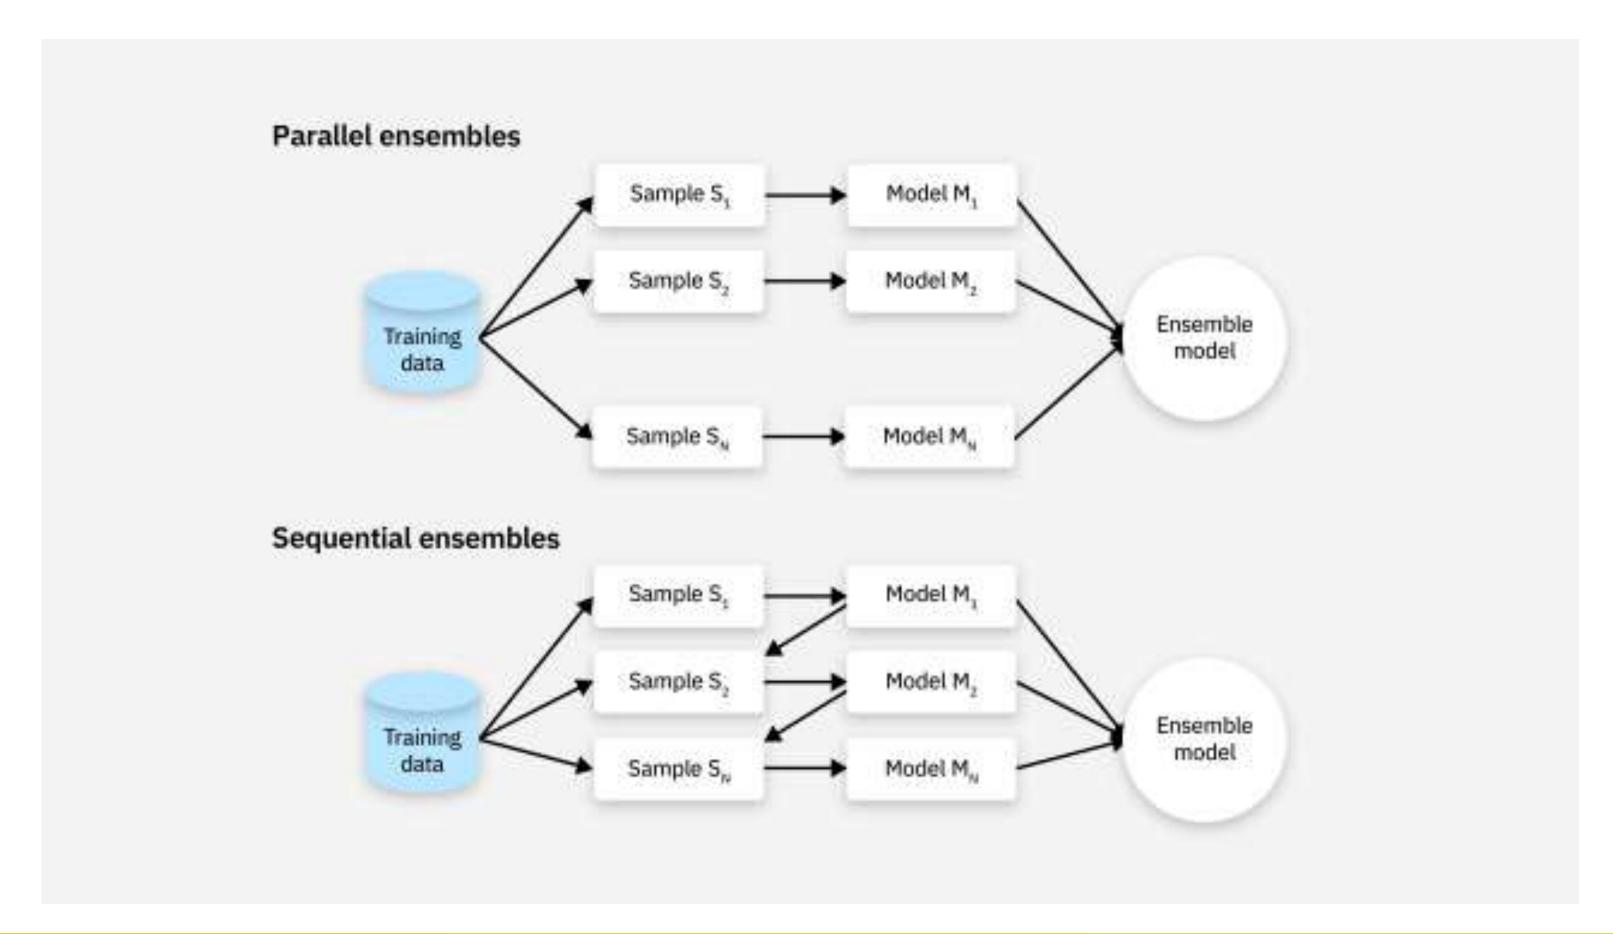

## Types of Ensemble

## **Basic Ensemble Techniques and Methods**

- 1. Max Voting
- 2. Averaging
- 3. Weighted Average

- 1. Bootstrap
- 2. Bagging
- 3. Stocking

#### **Max Voting**

## Ensemble Learning Methods – Bagging

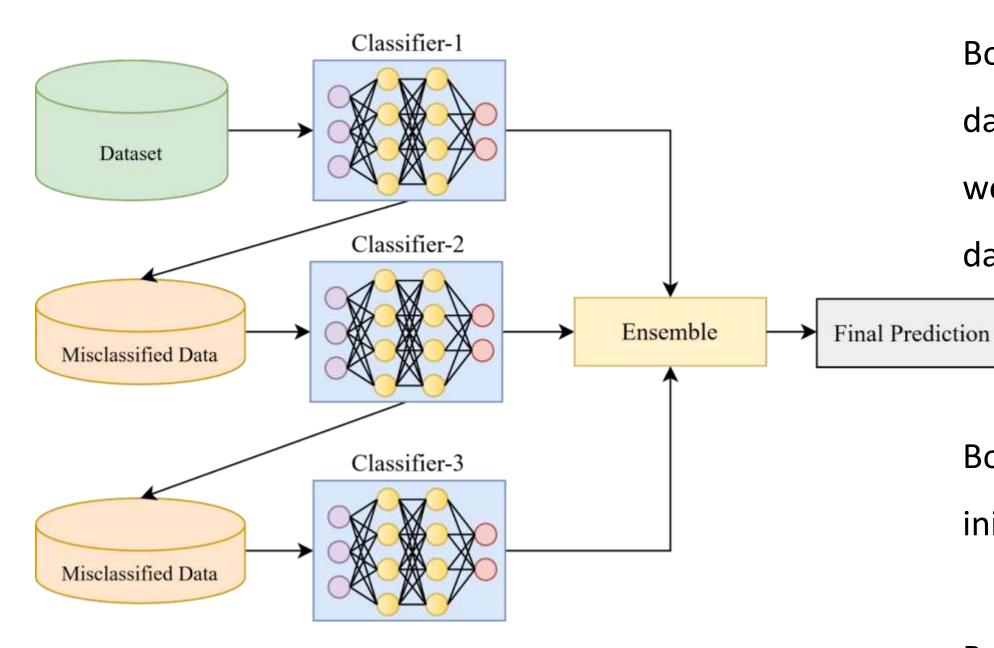

Subsamples from a dataset are created and they are called "bootstrap sampling." To put it simply, random subsets of a dataset are created using replacement, meaning that the same data point may be present in several subsets.

## Ensemble Learning Methods - Boosting

Boosting trains a learner on some initial dataset, d. The resultant learner is typically weak, misclassifying many samples in the dataset.

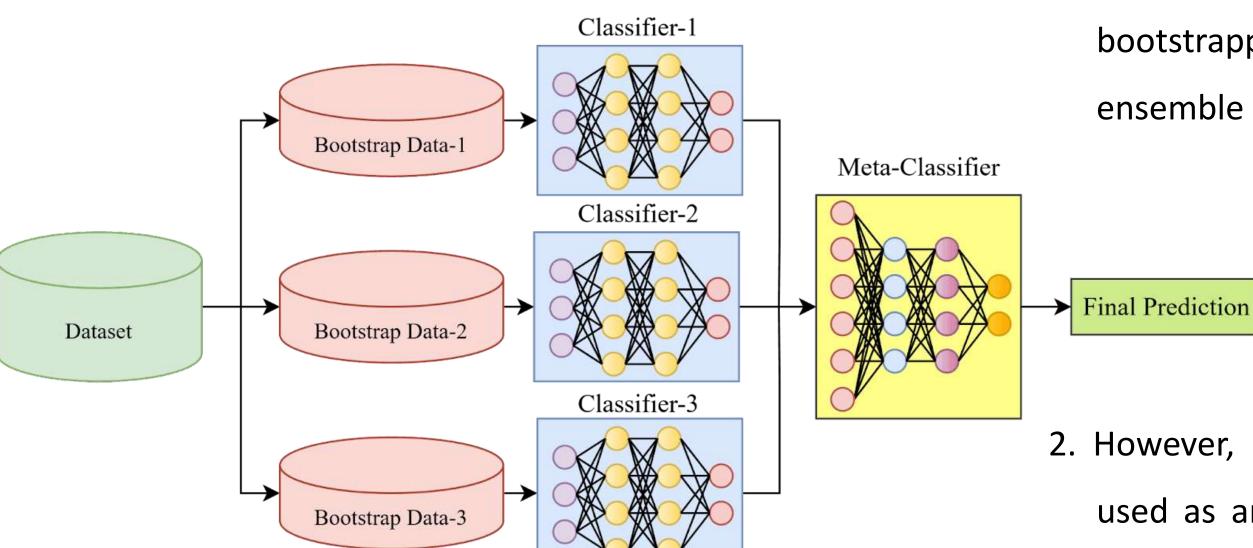

Boosting then samples instances from the initial dataset to create a new dataset  $(d_2)$ 

misclassified Boosting prioritizes data instances from the first model or learner. A new learner is trained on this new dataset  $d_2$ .

## Ensemble Learning Methods - Stacking

1. The stacking ensemble method also involves creating bootstrapped data subsets, like the bagging ensemble mechanism for training multiple models.

2. However, here, the outputs of all such models are used as an input to another classifier, called metaclassifier, which finally predicts the samples.
